## Abstract

Here goes the Abstract in English of your thesis followed by a list of keywords. The Abstract is a concise summary of the content of the thesis (single page of text) and a guide to the most important contributions included in your thesis. The Abstract is the very last thing you write. It should be a self-contained text and should be clear to someone who hasn't (yet) read the whole manuscript. The Abstract should contain the answers to the main scientific questions that have been addressed in your thesis. It needs to summarize the adopted motivations and the adopted methodological approach as well as the findings of your work and their relevance and impact. The Abstract is the part appearing in the record of your thesis inside POLITesi, the Digital Archive of PhD and Master Theses (Laurea Magistrale) of Politecnico di Milano. The Abstract will be followed by a list of four to six keywords. Keywords are a tool to help indexers and search engines to find relevant documents. To be relevant and effective, keywords must be chosen carefully. They should represent the content of your work and be specific to your field or sub-field. Keywords may be a single word or two to four words.

**Keywords:** here, the keywords, of your thesis

# 1 | Introduction

The problem addressed by our contribution is the 3D-SBSBPP (3D Single Bin-Size Bin Packing Problem) which is strongly NP-hard and is the generalization of the one-dimensional bin packing problem [3].

Case study

Overview

## 2 | Literature review

# 3 | Problem description and mathematical formulation

In this thesis we address the 3D single bin-size bin packing problem (3D-SBSBPP). Starting from a set of items of different size the goal is to arrange them in the least amount of bins of a given fixed size without any overlap between each other. In addition to the standard formulation of the problem three additional practical constraints needs to be taken into account to satisfy the requests of our use-case:

- each item inside a bin should have static stability, meaning that every item should be supported either by the ground or by other items in the same bin
- the cage ratio of each used bin should be maximized
- each item can be rotated orthogonally along its vertical axis

Given a certain placement of items inside a bin of base  $W \times D$  with the top of the highest item being at  $z_{\max}$  and the sum of the volume of each item being  $V$ , the bin's cage ratio is defined as  $CR = \frac{V}{W \cdot D \cdot z_{\max}}$ . As seen in fig. 3.1, a high cage ratio means that even if a bin isn't fully occupied it could potentially be used as a base for other items. In a single bin setting maximizing cage ratio is equivalent to minimizing  $z_{\max}$ .

1. the sum of overlap area with every other item on which it is resting is greater then  $\beta_s$  times it's area
2. the number of its corners resting on another item is greater than 3 and condition 1 holds with a lower threshold  $\beta'_s < \beta$

Given the definitions of our practical constraints, a conceptual formulation of our model would be

$$\begin{array}{ll}
\text{minimize} & \text{number of used bins} \\
& \text{unused volume of each bin under } z_{\max} \\
\text{subject to} & \text{all items assigned to one and only one bin} \\
& \text{all items within the bin dimensions} \\
& \text{no overlaps between items in the same bin} \\
& \text{all items with vertical support}
\end{array}$$

We'll now introduce a mixed integer linear programming model for the 3D-SBSBPP that we then extend to include orthogonal rotations and vertical support constraints limited to condition of area support. Cage ratio isn't directly included in the proposed MILP formulation since the evaluation of the heuristic with the model was done in a single bin configuration where minimizing the maximum height of the bin is equivalent to minimizing the cage ratio.

### 3.1. 3D single bin-size bin packing problem

Let  $I = \{1, \dots, n\}$  be the set of items that needs to be packed,  $B = \{1, \dots, m\}$  the set of bins to evaluate of fixed dimensions  $W \times D \times H$ . Each item  $i \in I$  is characterized by a given width, depth and height  $(w_i, d_i, h_i)$ . Let us introduce three continuous variables that identify the position of the bottom front left corner of an item  $(x_i, y_i, h_i)$  as seen in fig. 3.3. We can now introduce a set of integer variables  $v_b$  which will be 1 if bin  $b \in B$  will be used in the solution and 0 otherwise. A set of integer variable  $u_{ib}$  which will be 1 if item  $i \in I$  will be placed in bin  $b \in B$  and 0 otherwise. In order to check for overlaps three sets of integer variables are introduced for each axis of possible overlap that are used to determine if there is a clear order of precedence on at least on axis. This formulation is also usually used in scheduling problems. The three sets of variables are  $x_{ij}^p$  which will take the value of one if item  $i \in I$  precedes item  $j \in I$  over axis  $x$  given that item  $i$  precedes item  $j$  if  $x_i + w_i \leq x_j$  and 0 otherwise. The other two sets are defined in a similar way over the remaining axis  $y_{ij}^p$  and  $z_{ij}^p$ . An additional set of continuous variables  $z_b^{\max}$  is introduced which will assume the value of the maximum  $x_i + h_i$  of the items  $i \in I$  placed in bin  $b \in B$ .

Figure 3.3: Coordinate system representation for a generic item  $i$  and its rotated clone  $i \in I^R$

The 3D-SBSBPP can then be formulated as a mixed-integer linear programming problem:

$$\min \quad \sum_{b \in B} (Hv_b + z_b^{max}) \quad (3.1)$$

$$\text{s.t.} \quad \sum_{b \in B} u_{ib} = 1 \quad \forall i \in I \quad (3.2)$$

$$u_{ib} \leq v_b \quad \forall i \in I, \forall b \in B \quad (3.3)$$

$$v_b \geq v_c \quad \forall (b, c) \in B : b < c \quad (3.4)$$

$$x_i + w_i \leq W \quad \forall i \in I \quad (3.5)$$

$$y_i + d_i \leq D \quad \forall i \in I \quad (3.6)$$

$$z_i + h_i \leq H \quad \forall i \in I \quad (3.7)$$

$$z_b^{max} \geq (z_i + h_i) - H(1 - u_{ib}) \quad \forall i \in I, \forall b \in B \quad (3.8)$$

$$(x_i + w_i) - x_j \leq W(1 - x_{ij}^p) \quad \forall i, j \in I \quad (3.9)$$

$$x_j - (x_i + w_i) + 1 \leq Wx_{ij}^p \quad \forall i, j \in I \quad (3.10)$$

$$(y_i + d_i) - y_j \leq D(1 - y_{ij}^p) \quad \forall i, j \in I \quad (3.11)$$

$$y_j - (y_i + d_i) + 1 \leq Dy_{ij}^p \quad \forall i, j \in I \quad (3.12)$$

$$(z_i + h_i) - z_j \leq H(1 - z_{ij}^p) \quad \forall i, j \in I \quad (3.13)$$

$$z_j - (z_i + h_i) + 1 \leq Hz_{ij}^p \quad \forall i, j \in I \quad (3.14)$$

$$x_{ij}^p + x_{ji}^p + y_{ij}^p + y_{ji}^p + z_{ij}^p + z_{ji}^p \geq u_{ib} + u_{jb} - 1 \quad \forall i, j \in I, \forall b \in B \quad (3.15)$$

The objective function 3.1 seeks to minimize the number of opened bins and the maximum heights of the opened bins. In a single bin configuration since all the volume mass is

concentrated inside one bin this also means that it maximises the cage ratio. Constraint 3.2 ensures that each item is packed in one and only one bin, while constraint 3.3 ensures that items are only packed in bins that are used in the solution. Since the solution has lots of symmetries with respects to the number of bins a symmetry breaking constraint 3.4 can be added on the opening of bins to improve solve times. Each item is also ensured to be placed inside the bin thanks to eqs. (3.5) to (3.7). The value of  $z_b^{max}$  is forced to converge to the maximum height of a given bin thanks to constraint 3.8. Constraints from 3.9 to 3.14 are used to define the precedence binary variables  $x_{ij}^p, y_{ij}^p, z_{ij}^p$  over each axis as described in the problem formulation. Constraint 3.15 then ensures that if two items are in the same bin then there needs to be at least one axis with a clear order of precedence, otherwise the two items would be overlapping each other.

## Othogonal rotations

Let us extend the definition of the bin packing problem without rotations with a new formulation which allows 90 degrees rotations of each item. Let  $I = I^O \cup I^R$  be the new set of items where  $I^O$  is the set of original non-rotated items and  $I^R$  is the set of items rotated by 90 degrees.

We can now rewrite constraint 3.2 as 3.16 to force only one for the item between the original and rotated to be part of the solution.

$$\sum_{b \in B} u_{ib} + \sum_{b \in B} u_{jb} = 1 \quad \forall j = i^R \in I \quad (3.16)$$

## Static stability constraints

We now extend the model introduced in ?? to add constraints addressing static stability.

### Additional Parameters

$\alpha_s$  : support area threshold

$\beta_s$  : support height tolerance

$\delta$  : discretization unit

$IB$  : the set of tuples  $(i, j, b)$  such that  $(i, j) \in I \wedge i \neq j$  and  $b \in B$

### Computed Parameters

$$\begin{aligned}
\gamma &= \max_{\forall i \in I} \{w_i, d_i\} : \text{maximum possible dimension of an item} \\
\Delta &= \left[ -\left\lfloor \frac{\gamma}{\delta} \right\rfloor, \left\lfloor \frac{\gamma}{\delta} \right\rfloor \right] : \text{set of possible distances between overlapping items} \\
O(i, j, h, k) &\rightarrow \mathbb{R}^+ : \text{discrete overlap function}
\end{aligned} \tag{3.17}$$

### Additional Variables

$$\begin{aligned}
s_{ij} &\begin{cases} 1, \text{if item } i \text{ can offer support to item } j \\ 0, \text{otherwise} \end{cases} & \forall (i, j) \in I \\
z_{ij}^c &\begin{cases} 1, \text{if } 0 \leq z_j - (z_i + h_i) \leq \beta_s \\ 0, \text{otherwise} \end{cases} & \forall (i, j) \in I \\
g_i &\begin{cases} 1, \text{if } z_i = 0 \\ 0, \text{otherwise} \end{cases} & \forall (i, j) \in I \\
s_{ijb}^{kh} &\begin{cases} 1, \text{if item } i \text{ receives support from item } j \\ \quad \text{when both are placed in bin } b \\ \quad \text{with distance } (k, h) \in \Delta \text{ between each other} \\ 0, \text{otherwise} \end{cases} & \forall (i, j) \in I
\end{aligned}$$

## Additional Constraints

$$z_j - (z_i + h_i) \leq \beta_s + H(1 - z_{ij}^c) \quad \forall (i, j) \in I : i \neq j \quad (3.18)$$

$$z_j - (z_i + h_i) \geq -\beta_s - H(1 - z_{ij}^c) \quad \forall (i, j) \in I : i \neq j \quad (3.19)$$

$$s_{ij} \leq z_{ij}^p \quad \forall (i, j) \in I \quad (3.20)$$

$$s_{ij} \leq z_{ij}^c \quad \forall (i, j) \in I \quad (3.21)$$

$$s_{ij} \geq z_{ij}^p + z_{ij}^c - 2 \quad \forall (i, j) \in I : i \neq j \quad (3.22)$$

$$\sum_{j \in I} s_{ij} \leq \sum_{b \in B} u_{ib} \quad \forall i \in I \quad (3.23)$$

$$z_i \leq H(1 - g_i) \quad \forall i \in I \quad (3.24)$$

$$\sum_{(k,h) \in \Delta, b \in B: O(i,j,k,h) \neq 0} s_{ijb}^{kh} \leq s_{ij} \quad \forall (i, j) \in I \quad (3.25)$$

$$\sum_{(k,h) \in \Delta: O(i,j,k,h) \neq 0} s_{ijb}^{kh} \leq u_{ib} \quad \forall (i, j, b) \in IB \quad (3.26)$$

$$\sum_{(k,h) \in \Delta: O(i,j,k,h) \neq 0} s_{ijb}^{kh} \leq u_{jb} \quad \forall (i, j, b) \in IB \quad (3.27)$$

$$(3.28)$$

We can then define a set of constraints which given a discretized placement  $s_{ijb}^{kh}$  limits the distance between  $i$  and  $j$  to a given continuous region in space delimited by a square of the dimension of our discretization unit  $\gamma$ . Given every  $(k, h) \in \Delta, (i, j, b) \in IB$  such that  $O(i, j, k, h) \neq 0$  the resulting constraints are defined in eqs. (3.29) to (3.32).

$$x_j - x_i \geq \gamma k - 2W(1 - s_{ijb}^{kh}) \quad (3.29)$$

$$x_j - x_i \leq \gamma(k + 1) + 2W(1 - s_{ijb}^{kh}) \quad (3.30)$$

$$y_j - y_i \geq \gamma h - 2D(1 - s_{ijb}^{kh}) \quad (3.31)$$

$$y_j - y_i \leq \gamma(h + 1) + 2D(1 - s_{ijb}^{kh}) \quad (3.32)$$

And finally we can introduce a feasibility constraint which ensures that every item that isn't on the ground is supported by some items in the same bin.

$$\sum_{(k,h) \in \Delta, b \in B, j \in I: i \neq j \wedge O(i,j,k,h) \neq 0} O(i, j, k, h) s_{ijb}^{kh} \geq \alpha_s w_i d_i - w_i d_i g_i \quad \forall i \in I \quad (3.33)$$

# 4 | Solution algorithms

In this chapter, we describe an heuristic algorithm to solve the 3D bin packing problem with vertical support. In section 4.1 we describe the concepts which will be used in the algorithm, like the definition of a state, insertions, and the feasibility of a solution. Since the 3D-BPP is NP-Hard an exhaustive search for a solution isn't practical so an heuristic search is conducted by combining a beam search algorithm described in section 4.2 and a constructive heuristic described in section 4.3. The proposed algorithm takes in input an initial feasible state (as defined in section 4.1.2) usually represented by the empty state (4.3) and outputs the best scoring state based on an ordering function defined in section 4.2.1.

## 4.1. State

States or packings are partial solutions to the 3D-BPP. Given the formal definition of the problem (3.1) a few new definitions are introduced to facilitate the algorithm's definition.

**Definition 4.1** (Unpacked item). *An item  $i \in I$  is unpacked **iff***

$$\sum_{b \in B} u_{ib} = 0$$

It is also assumed that variables identifying an item's position are independent between states (changes to their values in state  $s$  won't affect state  $s'$ ). In order to simplify the algorithm representation, rotations are handled by simply swapping the dimensions  $w_i$  and  $d_i$  of item  $i$  when needed.

A state  $s$  can then be defined as follows

- $U$ : the set of unpacked items
- $B$ : the set of used bins
- $Q = (q_1, q_2, \dots, q_b)$ : the set of supporting structures for each bin  $b \in B$

- $p$ : the insertion pending on this state (described by def. 4.4)

**Observation 4.1.** *Given two states  $s$  and  $s'$  we can have that  $|s.B| \neq |s'.B|$  since the number of bins is also a variable in the proposed heuristic*

We can also trivially define a function that determines if a state is a final state

**Definition 4.2.** *A state  $s$  is final if there are no more items to pack*

$$IsFinal(s) = \begin{cases} 1, & s.U = \emptyset \\ 0, & otherwise \end{cases} \quad (4.1)$$

Each used bin  $b$  has additional data associated to it that is contained in  $q_b \in s.Q$  which is used to store structures usefull to the constructive heuristic defined in section 4.3. Let us introduce the concept of packed items inside a bin:

**Definition 4.3 (Packed item).** *Given a state  $s$  and a bin  $b \in s.B$ , we say that item*

$$i \in I \text{ is packed in } b \text{ iff } u_{ib} = 1$$

Given a bin  $b \in s.B$  we can then define structure  $q_b$  as follows

- $J$ : the set of items that are packed inside  $b$
- $Z$ : the set of planes inside  $b$  (section 4.3)
- $T$ : the AABB Tree (section 4.1.1) representing the items inside  $b$

Both sets  $q_b.J$  and  $q_b.T$  contain the items packed in  $b$  but adding and accessing items in  $q_b.J$  has a time complexity of  $O(1)$  given an underlying implementation as HashSet while maintaining  $q_b.T$  usually has a time complexity of  $O(\log(|q_b.J|))$ . The AABB Tree inside this structure is included to allow for fast overlap checks between items and is further explained in sections 4.1.2 and 4.3.1.

#### 4.1.1. AABB Tree

In order to determine the feasibility of a given state, a way of checking for overlaps with items already placed is needed. Since our formulation of the problem only allows for 90 deg rotations over the z-axis. Every item in a solution, by the problem formulation (3.3), is contained inside a bounding box and this box is axis-aligned. An adequate structure to compute overlaps is then an Axis-Aligned Bounding Box Tree (AABB Tree) [1].

AABB Trees are bounding volume hierarchies typically used for fast collision detection and they usually offer a few operations:

- $AABBInsert(i)$ : which allows inserting an axis-aligned box  $i$  in the tree
- $AABBOverlaps(i)$ : which allows determining if an axis-aligned box  $i$  overlaps an element in the tree
- $AABBClosest(i, d)$ : which, given an axis-aligned box  $i$  and a direction  $d \in \{XP, XN, YP, YN, ZP, ZN\}$  along an axis, returns the closest element following that direction starting from the box  $i$

If the tree is properly balanced each operation on average has a time complexity of  $O(\log(n))$  where  $n$  is the number of elements in the tree. Maintaining an AABB Tree in the state allows us to do checks for feasibility during the construction of a solution (as detailed in 4.3.1 ) and feasibility checks on the final states to allow for error detection.

#### 4.1.2. Feasibility

A state  $s$  is said to be feasible if the currently packed items for every bin  $b \in s.B$  respects the constraints defined in the problem formulation (section 3.1). Since the proposed heuristic is constructive it is more convenient to define the concept of feasibility relative to a change in the state.

**Insertions** Given a state  $s$  and  $b \in s.B$ , an insertion of items is a set of items that are placed in  $b$  and have their  $z_i$  within a tolerance from a certain  $z$ .

**Definition 4.4 (Insertion).** *Given a state  $s$  and a tolerance  $\beta_s$  we define an insertion or placement  $p$  a tuple  $(b, I)$  where  $b$  is a bin and  $I$  is a set of items that are going to be packed in  $b$  such that,  $I \subseteq s.U \wedge \exists z(z \in \mathbb{Z} \wedge \forall i(i \in I \wedge |z_i - z| \leq \beta_s))$*

**Observation 4.2.** *Given a state  $s$  and an insertion  $p = (b, \emptyset)$  where  $b \notin s.B$ ,  $p$  is an insertion which will open bin  $b$  in  $s$ .*

**Definition 4.5 (Next).** *Let  $p$  be an insertion over a state  $s$  we can then define  $s' = Next(s, p)$  as the "copy" of state  $s$  with  $s'.p = p$ . And  $p$  is then pending insertion on  $s'$ .*

We can evaluate the changes to the score of a state based on its pending insertion without having to update all the structures for every evaluated state. This property will become apparent in section 4.2. We can then define an algorithm that applies a pending insertion  $p$  on a given state  $s$  with the help of a function  $OpenBin(b)$  which initializes a new

structure  $q_b$  with every element at its empty value. The proposed algorithm is shown in ??.

---

**Algorithm 1:** Commit
 

---

```

input  :  $s$ 
output:  $s'$ 
 $(b, I) \leftarrow s.p$ 
 $s' \leftarrow \text{Clone}(s)$  //Memory clone of  $s$ 
if  $b \in s'.B$  then
     $q_b \leftarrow (q_i \in s'.Q : i = b)$ 
     $q_b.J \leftarrow q_b.J \cup I$ 
     $s'.U \leftarrow s'.U \setminus I$ 
end
else Open a new bin
     $s'.B \leftarrow s'.B \cup b$ 
     $s'.Q \leftarrow s'.Q \cup \text{OpenBin}(b)$ 
end
 $s'.p \leftarrow \text{none}$ 
return  $s'$ 

```

---

**Insertion feasibility** An insertion  $p = (b, I)$  that is pending on a given state  $s$  is feasible if every inserted item  $i \in p.I$  satisfies the constraint of non-overlap (3.15), the constraint of support (3.33) and if it is placed within the size of the given bin.

---

**Algorithm 2:** Is Insertion Feasible
 

---

```

input  :  $b, I, z, I_{\text{support}}, I_{\text{upper}}$ 
output:  $\text{isFeasible}$ 
return  $\text{true}$ 

```

---

**State feasibility** Describe how to compute the sets efficiently to use the insertion feasibility logic

---

**Algorithm 3:** Is State Feasible
 

---

```

input  :  $s$ 
output:  $\text{isFeasible}$ 
return  $\text{true}$ 

```

---

**Proposition 4.1.** A state  $s'$  derived by committing a feasible insertion  $p$  to a feasible state  $s$  is feasible.

**Observation 4.3.** *We can always define the empty state  $s_e$  where*

$$\begin{cases} s_e.U = I \\ s_e.Q = \emptyset \\ s_e.B = \emptyset \end{cases}$$

*and it is always feasible*

## 4.2. Beam Search

Beam Search (BS) is a heuristic tree search algorithm designed for systems with limited memory where expanding every possible node is unfeasible. The idea behind BS is to conduct an iterative truncated breadth-first search where, at each iteration, only a limited number of  $k$  nodes is expanded. After the expansion, every new node needs to be evaluated and sorted in order to prune the number of nodes down to the  $k$  best ones. The algorithm keeps exploring until no further node can be expanded.

To perform BS one must define the node structure, an expansion function to generate new nodes from existing ones, a ranking between nodes, and a function to determine if a node is final.

A node in the tree can be represented as the state in section 4.1 and eq. (4.1) can be used to determine if a state is final. We also know that a new state  $s'$  derived by  $s$  by applying a feasible insertion  $p$  can be computed as in definition 4.5. This state expansion procedure, with the exception of empty insertions, will generate new states in our tree which will add a positive number of bins or packed items to the solution so, eventually, it will generate a final state.

If the starting state for the search is feasible every new state generated will be feasible and if a final state is found it will be feasible ( proposition 4.1). We also note that starting from state  $s$  the time complexity to compute feasible insertions can be lower than the complexity required to update the structures that will be used for further expansions (AABB Tree insertion and balancing, memory cloning, etc.) so we modified the standard BS algorithm to separate the expansion phase from the commit phase.

Given  $S^0$  the set of initial states and  $k$  the number of best states to expand at each iteration, the described procedure is represented by algorithm 4. As observed in observation 4.3 it's possible to start the search from  $S^0 = \{s_e\}$ .

---

**Algorithm 4:** Beam search

---

```

input :  $S^0, k$ 
output:  $s_{best}$ 
 $S^t \leftarrow S^0$ 
 $S_{final} \leftarrow \emptyset$ 
repeat
     $S^{t+1} \leftarrow Expand(S^t)$  (algo. 5)
     $S_{final} \leftarrow S_{final} \cup \{s \in S^{t+1} : IsFinal(s)\}$  (def. 4.2)
     $S^{t+1} \leftarrow S^{t+1} \setminus S_{final}$ 
     $S^{t+1} \leftarrow Sort(S^{t+1})$  (sec. 4.2.1)
     $S^t \leftarrow \emptyset$ 
     $i \leftarrow 0$ 
    forall  $s \in S^{t+1}$  do
         $S^t \leftarrow S^t \cup Commit(s)$  (algo. ??)
         $i \leftarrow i + 1$ 
        if  $i > k$  then
            break
        end
    end
until  $S^t \neq \emptyset$ 
 $S_{final} \leftarrow Sort(S_{final})$ 
return first element of  $S_{final}$ 

```

---

**State Expansion** An expansion of a state  $s$  can be seen as a new set of states  $S_{new}$  derived by a set of feasible insertions. In order to determine these insertions, an underlying heuristic is used (described in section 4.3).

The main idea in this phase of the algorithm is to find feasible insertions in all the bins for items that still need to be packed and that are of the same height. With this approach, the solutions given by the algorithm will start by trying to fill lower layers with items of the same height if possible and they'll become more heterogeneous in upper layers where the classes of height will start to mix up. The underlying heuristic will also use a scoring mechanism to select the best insertions for a given class of heights in order to avoid having too many states to sort.

Given a set of items  $I$  and a tolerance  $\beta_s$  we can introduce an algorithm to group them by their shap and produce a set  $G$  of tuples  $(h, I')$  where  $h$  is the hash summarizing the shape of the group and  $I'$  is the set of items grouped as in algo. ??.

Once items are grouped by shape the best insertion for each class of items can be computed for each open bin. If no insertion is possible in any bin, then the only viable insertion is the bin opening insertion (observation 4.2). The described procedure is detailed in algo. 5.

---

**Algorithm 5:** Expand
 

---

**input** :  $S$ 
**output:**  $S_{new}$ 
**forall**  $s \in S$  **do**
 $S_{new} \leftarrow \emptyset$ 
 $G \leftarrow \text{GroupByHash}(s.U)$  (algo. ??)

 $placed \leftarrow false$ 
**forall**  $(h, I) \in G$  **do**
**forall**  $q_b \in s.Q$  **do**
 $P \leftarrow \text{SPBestInsertion}(q_b, I)$  (algo. 7)

**if**  $P \neq \emptyset$  **then**
 $placed \leftarrow true$ 
**forall**  $p \in P$  **do**
 $S_{new} \leftarrow S_{new} \cup \text{Next}(s, p)$  (def. 4.5)

**end**
**end**
**end**
**end**
**if**  $placed = false$  **then**
 $\text{Open a new bin with index } |s.B|$  (oss. 4.2)

 $S_{new} \leftarrow S_{new} \cup \text{Next}(s, (|s.B|, \emptyset))$ 
**end**
**end**
**return**  $S_{new}$ 

---

#### 4.2.1. Scoring States

In order to sort states, a scoring function needs to be defined over them. Since the scoring of the states is what will influence the final solution the most, parameters that are directly related to minimizing the objective function are selected.

In the proposed solution to handle multiple objective functions, lexicographic ordering is used.

---

**Algorithm 6:** Group By Hash

---

```

input  :  $I$ 
output:  $G$ 
 $G \leftarrow \emptyset$ 
forall  $i \in I$  do
     $generate \leftarrow \text{true}$ 
    forall  $(h, I') \in G$  do
        if  $h = \text{hash}(w_i, d_i, h_i)$  then
             $generate \leftarrow \text{false}$ 
             $I' \leftarrow I' \cup i$ 
            break
        end
    end
    if  $generate = \text{true}$  then
         $G \leftarrow G \cup (\text{hash}(w_i, d_i, h_i), \{i\})$ 
    end
end
return  $G$ 

```

---

**Definition 4.6.** Let  $f_1(s), f_2(s), f_i(s), \dots, f_n(s)$  be objective functions ordered by precedence based on index  $i$ , then

$$s < s' \text{ iff } \exists j \in \mathbb{Z} : \begin{cases} f_j(s) < f_j(s') \\ f_k(s) = f_k(s'), \quad \forall k \in \mathbb{Z} : 0 \leq k < j \end{cases}$$

Scoring metrics for each state  $s$  that we want to evaluate can then be computed in the *Next* algorithm by considering the contents of the pending insertions and updating each parameter differentially.

The defined ordering utilized is the following:

- $f_1(s) = -|s.B|$ : we prefer states that opened fewer bins.
- $f_2(s) = \text{avgvol}(s)$ : we prefer states that have packed more average volume between bins.
- $f_3(s) = \text{avgcageratio}(s)$ : we prefer states that have better average cage ratio (def. ??) between bins.

### 4.3. Support Planes

Support Planes (SP) is a heuristic detailed in the following section based on an underlying 2DBPP heuristic which is used to evaluate feasible insertions starting from a given state. Since the insertions must be feasible SP maintains an internal structure to facilitate the check for feasibility. The idea at the base of SP is to build a solution to the 3DBPP by filling 2D planes called *support planes*.

Each support plane can be characterized by the triple  $S_z = (z, I_{support}, I_{upper})$  where

- $z$ : the height of the plane
- $I_{support}$ : the set of the items that can offer support to items placed on the plane
- $I_{upper}$ : the set of items that will be obstacles to potential new items placed on the plane

Let *coords* be the set of possible coordinate changes which allow for the problem to evaluate insertions starting from different corners of the bin.

Given a function  $IsFeasible(i, bin, I_{support}, I_{upper}, aabb)$  which evaluates if a packing of item  $i$  in bin  $bin$  is feasible, and the function  $ComparePacking(p, p')$  which defines a ranking over insertions in the same plane, the SP algorithm can be written as algorithm 7.

**Algorithm 7:** SP Best Insertion

---

**input** :  $s_b, I$   
**output:**  $placement$   
 $placement \leftarrow \emptyset$   
**forall**  $S_z \in planes$  **do**  
     $I_p \leftarrow I \setminus \{i \in I : z + i.h > H_b\}$   
    **forall**  $change \in coords$  **do**  
         $I'_{upper} \leftarrow CoordinateChange(change, I_{upper})$   
         $I'_p \leftarrow CoordinateChange(change, I_p)$   
         $P' \leftarrow SPPackPlane(W_b, D_b, I'_{upper}, I'_p)$  (Algorithm 8)  
         $P \leftarrow CoordinateChange(change, P')$   
         $P \leftarrow \{i \in P : IsFeasible(i, bin, I_{support}, I_{upper}, aabb)\}$   
        **if**  $ComparePacking(placement, P)$  **then**  
             $placement \leftarrow P$   
        **end**  
    **end**  
    **if**  $placement \neq \emptyset$  **then**  
        **return**  $placement$   
    **end**  
**end**  
**return**  $placement$

---

To evaluate a packing on a plane a heuristic to solve the 2DBPP is used with the introduction of fixed insertions which represent items on other planes that will be obstacles in the current one.

Given the dimensions of the 2D bin  $(W_b, D_b)$ , the set of obstacles  $I_o$  and the set of items to pack  $I_p$  a new insertion can be computed following algorithm 8

---

**Algorithm 8:** SP Pack Plane

---

**input** :  $W_b, D_b, I_o, I_p$ **output:**  $P$  $P \leftarrow \emptyset$  $2dPacking \leftarrow \emptyset$ **foreach**  $i \in I_o$  **do**    //Initialize the 2D bin packing instance with each obstable already  
    placed     $2DPlaceRect(2dPacking, i)$ **end****repeat**

//Pack untill full

 $p \leftarrow 2DPackRect(2dPacking, W_b, D_b, i)$      $P \leftarrow P \cup \{p\}$ **until**  $p \neq \emptyset$ **return**  $P$ 

---

**Commit Extension** We now describe an extension to *Commit* (algo. ??) to update the structures needed by SP.

When a plane is filled, new insertions become less likely to be feasible. To avoid evaluating planes where no insertion is possible a mechanism to prune dead planes can be introduced.

Since best insertions for a bin are always evaluated by considering lower planes first, if all the insertions in *Expand* (algo. 5) happened over a  $z_{min}$  then we can safely remove the opened planes with  $z < z_{min}$  for that bin. Let us introduce a  $z_{min}$  variable carried over in  $q_b$  for each bin, which is updated during the *Expand* phase with the minimum  $z$  of all the insertions on bin  $b$ . Once the best states are computed and *Commit* is called we can then use its value to prune planes in each  $q_b$ . Other operations are also necessary in the *Commit* algorithm to allow SP to update its data structures accordingly to the insertion.

Given a state  $s$  and an insertion  $p$  where each packed item  $i \in p.I$  in bin  $b$  has  $z_i$  within tolerance of  $z$  and the minimum height for the considered bin  $q_b.z_{min}$ . The algorithm which updates the structures for a given bin  $b$  is represented by algorithm 9. This new algorithm can be used as the last step of the *Commit* algorithm for each  $b \in s'.B$ .

---

**Algorithm 9:** SP Apply and Filter
 

---

```

input  :  $s, p, z, z_{min}, \beta_s$ 
output:  $s$ 
 $q_b \leftarrow (q_i \in s.Q : i = p.b)$ 
//Filter bad planes
 $q_b.Z \leftarrow q_b.Z \setminus \{(z', I_{support}, I_{upper}) \in q_b.Z : z' < z_{min}\}$ 
//Apply insertion
forall  $i \in p.I$  do
   $q_b.T \leftarrow \text{InsertAABB}(i, q_b.T)$  //If balanced  $O(\log(n))$ 
   $generate \leftarrow true$ 
  forall  $(z', I_{support}, I_{upper}) \in q_b.Z$  do
    //Based on the distance from the top of the item
     $dz \leftarrow z' - (z_i + h_i)$ 
    if  $0 \leq dz \leq \beta_s$  then
       $generate \leftarrow false$ 
       $I_{support} \leftarrow I_{support} \cup i$ 
    end
    else if  $dz < 0$  then
       $I_{upper} \leftarrow I_{upper} \cup i$ 
    end
  end
  if  $generate$  then
     $q_b.Z \leftarrow q_b.Z \cup (z_i + h_i, \{i\}, \emptyset)$ 
  end
end
return  $s$ 

```

---

#### 4.3.1. Scoring Insertions

# 5 | Computational experiments

## 5.1. Model validation

Table 5.1: Comparison with MILP model on limited set of boxes

N	Group By Hash		Single Placement		MILP Model

# B | Appendix B

It may be necessary to include another appendix to better organize the presentation of supplementary material.

## List of Figures

3.1	Cage ratio of two different bin configurations . . . . .	6
3.2	Rappresentation of an item with vertical support given $\beta_s = 0.5, \alpha_s$ . . . .	6
3.3	Coordinate system representation for a generic item $i$ and it's rotated clone $i \in I^R$ . . . . .	8

## List of Tables

5.1	Comparison with MILP model on limited set of boxes . . . . .	25
5.2	Summary of use-case tests . . . . .	26
A.1	Use-case tests . . . . .	32
A.2	Use-case tests . . . . .	33
A.3	Use-case tests . . . . .	34
A.4	Use-case tests . . . . .	35
A.5	Use-case tests . . . . .	36
A.6	Use-case tests . . . . .	37
A.7	Use-case tests . . . . .	38
A.8	Use-case tests . . . . .	39
