## Abstract

Here goes the Abstract in English of your thesis followed by a list of keywords. The Abstract is a concise summary of the content of the thesis (single page of text) and a guide to the most important contributions included in your thesis. The Abstract is the very last thing you write. It should be a self-contained text and should be clear to someone who hasn't (yet) read the whole manuscript. The Abstract should contain the answers to the main scientific questions that have been addressed in your thesis. It needs to summarize the adopted motivations and the adopted methodological approach as well as the findings of your work and their relevance and impact. The Abstract is the part appearing in the record of your thesis inside POLITesi, the Digital Archive of PhD and Master Theses (Laurea Magistrale) of Politecnico di Milano. The Abstract will be followed by a list of four to six keywords. Keywords are a tool to help indexers and search engines to find relevant documents. To be relevant and effective, keywords must be chosen carefully. They should represent the content of your work and be specific to your field or sub-field. Keywords may be a single word or two to four words.

**Keywords:** here, the keywords, of your thesis

# 1 | Introduction

The problem addressed by our contribution is the 3D-SBSBPP (3D Single Bin-Size Bin Packing Problem) which is strongly NP-hard and is the generalization of the one-dimensional bin packing problem [9].

Case study

Overview

## 2 | Literature review

### Static stability

Static stability or vertical support received most of its contributions from the fields of Pallet Loading Problems (PLP) and Cargo Loading Problems (CLP). In [3] a second order cone programming formulation was provided as a solution to a spacing problem between layers of a pallet. The publication further described the concept of minimizing the area of overlap between items of different layers to increase spacing between items of the same layer and increase the ammount of potential support for higher layers. In [10] a formulation of the CLP was given with practical constraints like weight distrubtion, non-regular container shapes and vertical stability through vertex support.

# 3 | Problem description and mathematical formulation

In this thesis we address the 3D single bin-size bin packing problem (3D-SBSBPP) with the addition of a few practical constraints. Starting from a set of items of different size the goal is to arrange them in the least ammount of bins of a given fixed size without any overlap between eachother. In addition to the standard formulation of the problem three additional practical constraints need to be taken into account to satisfy the requests of our use-case:

- each item inside a bin should have static stability, meaning that every item should be supported either by the ground or by other items in the same bin
- the cage ratio of each used bin should be maximized
- each item can be rotated orthogonally along its vertical axis

Given a certain placement of items inside a bin of base  $W \times D$  with the top of the highest item being at  $z_{\max}$  and the sum of the volume of each item being  $V$ , the bin's cage ratio is defined as eq. (3.1).

$$\text{CR} = \frac{V}{W \cdot D \cdot z_{\max}} \quad (3.1)$$

A high cage ratio means that even if a bin isn't fully occupied it could potentially be used as a base for other structures, a property which is desirable in some industrial setting. It is also noted that in a single bin configuration, maximizing cage ratio is equivalent to minimizing  $z_{\max}$ . A visual rappresentation of the cage ratio metric is provided in fig. 3.1.

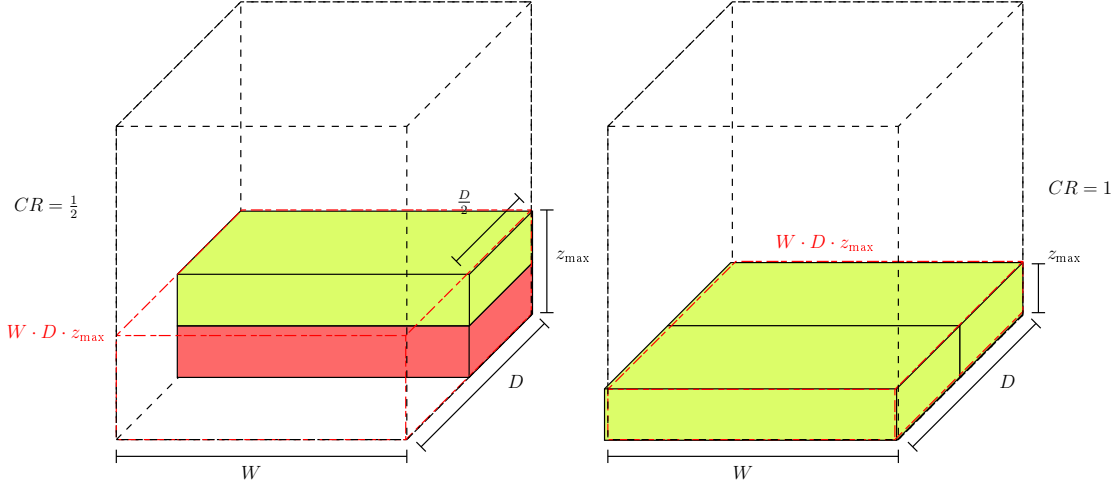

Figure 3.1: Cage ratio of two different bin configurations

Our notion of vertical support stems from rules imposed by the industry and from the literature on Pallet Loading Problems and Container Loading Problems where stability is usually ensured between horizontal or vertical slices of items as a constraint on the minimum ammount of area which rests on other items (as for ex. [3, 7, 10]). Given a support area threshold which is usually equal to  $\alpha_s = 0.7$  and a tolerance which in our case is equal to  $\beta_s = 1\text{cm}$ , we can define an item as supported if

1. the sum of the overlap area over the XY-plane with every other item on which it is resting is greater then  $\alpha_s$  times it's base area (area support)
2. the number of its corners resting on another item is greater than 3 and condition 1 holds with a lower threshold  $\alpha'_s < \alpha_s$  (vertex support)

A visual rappresentation of the condition of support is illustrated in fig. 3.2.

Figure 3.2: Rappresentation of an item with vertical support given  $\alpha_s = 0.5, \beta_s$

Given the definitions of our practical constraints, a conceptual formulation of our model would be

$$\begin{array}{ll}
\text{minimize} & \text{number of used bins} \\
& \text{unused volume of each bin under } z_{\max} \\
\text{subject to} & \text{all items assigned to one and only one bin} \\
& \text{all items within the bin dimensions} \\
& \text{no overlaps between items in the same bin} \\
& \text{all items with vertical support}
\end{array}$$

In section 3.1 a mixed integer linear programming model for the 3D-SBSBPP is presented and it's later extended to include orthogonal rotations in section 3.1.1 and vertical support constraints limited to condition 1 (area support) in section 3.1.2. Cage ratio isn't directly included in the proposed MILP formulation since the evaluation of the heuristic with the model was done in a single bin configuration where minimizing the maximum height of the bin is equivalent to minimizing the cage ratio.

### 3.1. 3D single bin-size bin packing problem

Let  $I = \{1, \dots, n\}$  be the set of items that needs to be packed,  $B = \{1, \dots, m\}$  the set of bins to evaluate of fixed dimensions  $W \times D \times H$ . Each item  $i \in I$  is characterized by a given width, depth and height  $(w_i, d_i, h_i)$ . Let us introduce three continuous variables that identify the position of the bottom front left corner of an item  $(x_i, y_i, h_i)$  as seen in fig. 3.3. We can now introduce a set of integer variables  $v_b$  which will be 1 if bin  $b \in B$  will be used in the solution and 0 otherwise. A set of integer variable  $u_{ib}$  which will be 1 if item  $i \in I$  will be placed in bin  $b \in B$  and 0 otherwise. In order to check for overlaps three sets of integer variables are introduced for each axis of possible overlap that are used to determine if there is a clear order of precedence on at least on axis. This formulation is also usually used in scheduling problems. The three sets of variables are  $x_{ij}^p$  which will take the value of one if item  $i \in I$  precedes item  $j \in I$  over axis  $x$  given that item  $i$  precedes item  $j$  if  $x_i + w_i \leq x_j$  and 0 otherwise. The other two sets are defined in a similar way over the remaining axis  $y_{ij}^p$  and  $z_{ij}^p$ . An additional set of continuous variables  $z_b^{\max}$  is introduced which will assume the value of the maximum  $x_i + h_i$  of the items  $i \in I$  placed in bin  $b \in B$ .

Figure 3.3: Coordinate system representation for a generic item  $i$  and its rotated clone  $i \in I^R$

The 3D-SBSBPP can then be formulated as a mixed-integer linear programming problem:

$$\min \sum_{b \in B} (Hv_b + z_b^{max}) \quad (3.2)$$

$$\text{s.t.} \quad \sum_{b \in B} u_{ib} = 1 \quad \forall i \in I \quad (3.3)$$

$$u_{ib} \leq v_b \quad \forall i \in I, \forall b \in B \quad (3.4)$$

$$v_b \geq v_c \quad \forall (b, c) \in B : b < c \quad (3.5)$$

$$x_i + w_i \leq W \quad \forall i \in I \quad (3.6)$$

$$y_i + d_i \leq D \quad \forall i \in I \quad (3.7)$$

$$z_i + h_i \leq H \quad \forall i \in I \quad (3.8)$$

$$z_b^{max} \geq (z_i + h_i) - H(1 - u_{ib}) \quad \forall i \in I, \forall b \in B \quad (3.9)$$

$$(x_i + w_i) - x_j \leq W(1 - x_{ij}^p) \quad \forall i, j \in I \quad (3.10)$$

$$x_j - (x_i + w_i) + 1 \leq Wx_{ij}^p \quad \forall i, j \in I \quad (3.11)$$

$$(y_i + d_i) - y_j \leq D(1 - y_{ij}^p) \quad \forall i, j \in I \quad (3.12)$$

$$y_j - (y_i + d_i) + 1 \leq Dy_{ij}^p \quad \forall i, j \in I \quad (3.13)$$

$$(z_i + h_i) - z_j \leq H(1 - z_{ij}^p) \quad \forall i, j \in I \quad (3.14)$$

$$z_j - (z_i + h_i) + 1 \leq Hz_{ij}^p \quad \forall i, j \in I \quad (3.15)$$

$$x_{ij}^p + x_{ji}^p + y_{ij}^p + y_{ji}^p + z_{ij}^p + z_{ji}^p \geq u_{ib} + u_{jb} - 1 \quad \forall i, j \in I, \forall b \in B \quad (3.16)$$

The objective function 3.2 seeks to minimize the number of opened bins and the maximum heights of the opened bins. In a single bin configuration since all the volume mass is

concentrated inside one bin this also means that it maximises the cage ratio. Constraint 3.3 ensures that each item is packed in one and only one bin, while constraint 3.4 ensures that items are only packed in bins that are used in the solution. Since the solution has lots of symmetries with respect to the number of bins a symmetry breaking constraint 3.5 can be added on the opening of bins to improve solve times. Each item is also ensured to be placed inside the bin thanks to eqs. (3.6) to (3.8). The value of  $z_b^{max}$  is forced to converge to the maximum height of a given bin thanks to constraint 3.9. Constraints from 3.10 to 3.15 are used to define the precedence binary variables  $x_{ij}^p$ ,  $y_{ij}^p$ ,  $z_{ij}^p$  over each axis as described in the problem formulation. Constraint 3.16 then ensures that if two items are in the same bin then there needs to be at least one axis with a clear order of precedence, otherwise the two items would be overlapping each other.

### 3.1.1. Othogonal rotations

Let us extend the definition of the bin packing problem without rotations with a new formulation which allows 90 degrees rotations of each item. Let  $I = I^O \cup I^R$  be the new set of items where  $I^O$  is the set of original non-rotated items and  $I^R$  is the set of items rotated by 90 degrees. Given the set of tuples  $(i, j) \in I^{OR}$  where  $i$  is the original item with dimensions  $(w_i, d_i, h_i)$  and  $j$  is the corresponding rotated clone with dimensions  $(w_j, d_j, h_j) = (d_i, w_i, h_i)$ , we can now rewrite constraint 3.3 as 3.17 to force only one of them to be part of the solution.

$$\sum_{b \in B} u_{ib} + \sum_{b \in B} u_{jb} = 1 \quad \forall (i, j) \in I^{OR} \quad (3.17)$$

### 3.1.2. Discrete vertical support formulation

We now extend the model to address the constraint of static support. In the literature there are some mathematical formulations that tackle the concept of area support, and in some cases vertex support. In Elhedhli et al. a SOCP formulation of the support constraint was used but was limited to the problem of spacing between layers with one of the layers being fixed in position, in our case a similar formulation would lead to a non-linear support constraint. By introducing a discretization over the XY-plane a linear version of the constraint can be formulated similar to the one proposed in Kurpel et al. without the need to discretize the z-axis as well.

Let us introduce some additional parameters to the model, let  $0 \leq \alpha_s \leq 1$  be the amount of area that an item needs to have supported by other items and let  $\beta_s$  be the height

tollerance to consider one item as being close enough to support another item (as seen in fig. 3.2). In addition to the support parameters an additional parameter  $\delta$  is given which represents the discretization unit used to partition the XY-plane. Let  $I^B$  be the set of all the tuples  $(i, j, b)$  such that  $(i, j) \in I \wedge i \neq j$  and  $b \in B$ . We can now compute a few additional parameters that will be used to reduce the number of constraints evaluated by the model. Let  $\gamma$  be the maximum size over a dimension on the XY-plane between all the items as eq. (3.18), and let  $\Delta$  be the set of all possible distances between the origins of two items along one discretized axis as eq. (3.19).

$$\gamma = \max_{\forall i \in I} \{w_i, d_i\} \quad (3.18)$$

$$\Delta = \left[ -\left\lfloor \frac{\gamma}{\delta} \right\rfloor, \left\lfloor \frac{\gamma}{\delta} \right\rfloor \right] \quad (3.19)$$

Let  $O(i, j, h, k) \rightarrow \mathbb{R}^+$  be a function that computes the ammount of overlap between two items  $(i, j) \in I$  given the discretized distance between each other  $(h, k) \in \Delta$  such that  $x_j = x_i + \delta h$  and  $y_j = y_i + \delta k$  which returns the area of overlap or 0 otherwise.

Additional new variables need to be added to the ones of the original model, let  $s_{ij}$  be a set of binary variables which will assume value 1 if item  $i \in I$  can offer support to item  $j \in I$  and 0 otherwise. A new set of binary variables  $z_{ij}^c$  will be 1 if item  $i \in I$  is close w.r.t. the z-axis to item  $j \in I$ , which would mean that  $z_j - (z_i + h_i) \leq \beta_s$ , and 0 otherwise. Let us then introduce a new set of binary variables  $g_i$  which will assume value 1 if item  $i \in I$  will be on the ground or 0 otherwise and a set of binary variables  $s_{ijb}^{kh}$  that will assume value 1 if item  $i \in I$  will receive support from item  $j \in I$  and both will be placed in bin  $b \in B$  with a discretized distance of  $(k, h) \in \Delta$  between eachother and 0 otherwise.

Given all the additional parameters and variables introduced, a new formulation of the model can be given with the same objective function 3.2 and the constraints in section 3.1

with the addition of the following constraints:

$$z_j - (z_i + h_i) \leq \beta_s + H(1 - z_{ij}^c) \quad \forall (i, j) \in I : i \neq j \quad (3.20)$$

$$z_j - (z_i + h_i) \geq -\beta_s - H(1 - z_{ij}^c) \quad \forall (i, j) \in I : i \neq j \quad (3.21)$$

$$s_{ij} \leq z_{ij}^p \quad \forall (i, j) \in I \quad (3.22)$$

$$s_{ij} \leq z_{ij}^c \quad \forall (i, j) \in I \quad (3.23)$$

$$s_{ij} \geq z_{ij}^p + z_{ij}^c - 2 \quad \forall (i, j) \in I : i \neq j \quad (3.24)$$

$$\sum_{j \in I} s_{ij} \leq \sum_{b \in B} u_{ib} \quad \forall i \in I \quad (3.25)$$

$$z_i \leq H(1 - g_i) \quad \forall i \in I \quad (3.26)$$

$$\sum_{(k,h) \in \Delta, b \in B: O(i,j,k,h) \neq 0} s_{ijb}^{kh} \leq s_{ij} \quad \forall (i, j) \in I \quad (3.27)$$

$$\sum_{(k,h) \in \Delta: O(i,j,k,h) \neq 0} s_{ijb}^{kh} \leq u_{ib} \quad \forall (i, j, b) \in I^B \quad (3.28)$$

$$\sum_{(k,h) \in \Delta: O(i,j,k,h) \neq 0} s_{ijb}^{kh} \leq u_{jb} \quad \forall (i, j, b) \in I^B \quad (3.29)$$

Constraints 3.20 and 3.21 ensure that  $z_{ij}^c$  is forced to 1 only when the distance over the z-axis between item  $i$  and item  $j$  is within the range  $[-\beta_s, \beta_s]$ . The value of  $s_{ij}$  is then assigned to the logical equation  $z_{ij}^p \wedge z_{ij}^c$  thanks to constraints from 3.22 to 3.24. Since some items could be left out of the solution due to the formulation of orthogonal rotations, we also ensure that support can only come from placed items thanks to constraint 3.25. Constraint 3.26 together with the hard constraint of support that will be introduced ensures that  $g_i$  assumes value 1 if item  $i$  is on the ground. Constraints from 3.27 to 3.29 ensure that if a discretized support decision  $s_{ijb}^{kh}$  is 1 then every subscript of that variable must be true in the non-discretized model, so item  $i$  can give discretized support to item  $j$  in bin  $b$  if both items are assigned to bin  $b$  and if  $i$  can give support to item  $j$ . They also force the selection of only one possible combination of  $(h, k) \in \Delta$  for which  $i$  gives support to  $j$  in bin  $b$ .

We can then define a set of constraints which given a discretized placement  $s_{ijb}^{kh}$  limits the distance between  $i$  and  $j$  to a given continuous region in space delimited by a square of the dimension of our discretization unit  $\delta$ . Given every tuple of possible discretized distances between items  $(k, h) \in \Delta$  and every tuple of different pairs of items in the same bin  $(i, j, b) \in I^B$  such that the items would overlap over the discretized plane XY for a non-null region ( $O(i, j, k, h) \neq 0$ ) the resulting constraints are defined in eqs. (3.30)

to (3.33).

$$x_j - x_i \geq \gamma k - 2W(1 - s_{ijb}^{kh}) \quad (3.30)$$

$$x_j - x_i \leq \gamma(k + 1) + 2W(1 - s_{ijb}^{kh}) \quad (3.31)$$

$$y_j - y_i \geq \gamma h - 2D(1 - s_{ijb}^{kh}) \quad (3.32)$$

$$y_j - y_i \leq \gamma(h + 1) + 2D(1 - s_{ijb}^{kh}) \quad (3.33)$$

And finally we can introduce a feasibility constraint which ensures that every item that isn't on the ground is supported by other items placed beneath it by at least  $\alpha_s$  times its area, which corresponds to condition 1 of the practical constraint of vertical support.

$$\sum_{(k,h) \in \Delta, b \in B, j \in I: i \neq j \wedge O(i,j,k,h) \neq 0} O(i,j,k,h) s_{jib}^{kh} \geq \alpha_s w_i d_i - w_i d_i g_i \quad \forall i \in I \quad (3.34)$$

It is noted that since every combination of  $(i, j, b) \in I^B$  and  $(h, k) \in \Delta$  where  $O(i, j, k, h) = 0$  do not contribute to the support constraint, then they can be omitted from the formulation of the problem to reduce the number of constraints to evaluate.

# 4 | Solution algorithms

In this chapter, we describe an heuristic algorithm to solve the 3D bin packing problem with vertical support. In section 4.1 we describe the concepts which will be used in the algorithm, like the definition of a state, insertions, and the feasibility of a solution. Since the 3D-BPP is NP-Hard an exhaustive search for a solution isn't practical so an heuristic search is conducted by combining a beam search algorithm described in section 4.2 and a constructive heuristic described in section 4.3. The proposed algorithm takes in input an initial feasible state (as defined in section 4.1.2) usually represented by the empty state (4.3) and outputs the best scoring state based on an ordering function defined in section 4.2.1.

## 4.1. State

States or packings are partial solutions to the 3D-BPP. Given the formal definition of the problem (3.1) a few new definitions are introduced to facilitate the algorithm's definition.

**Definition 4.1** (Unpacked item). *An item  $i \in I$  is unpacked **iff***

$$\sum_{b \in B} u_{ib} = 0$$

It is also assumed that variables identifying an item's position are independent between states (changes to their values in state  $s$  won't affect state  $s'$ ). In order to simplify the algorithm representation, rotations are handled by simply swapping the dimensions  $w_i$  and  $d_i$  of item  $i$  when needed.

A state  $s$  can then be defined as follows

- $U$ : the set of unpacked items
- $B$ : the set of used bins
- $Q = (q_1, q_2, \dots, q_b)$ : the set of supporting structures for each bin  $b \in B$

- $p$ : the insertion pending on this state (described by def. 4.4)

**Observation 4.1.** *Given two states  $s$  and  $s'$  we can have that  $|s.B| \neq |s'.B|$  since the number of bins is also a variable in the proposed heuristic*

We can also trivially define a function that determines if a state is a final state

**Definition 4.2.** *A state  $s$  is final if there are no more items to pack*

$$IsFinal(s) = \begin{cases} 1, & s.U = \emptyset \\ 0, & otherwise \end{cases} \quad (4.1)$$

Each used bin  $b$  has additional data associated to it that is contained in  $q_b \in s.Q$  which is used to store structures usefull to the constructive heuristic defined in section 4.3. Let us introduce the concept of packed items inside a bin:

**Definition 4.3 (Packed item).** *Given a state  $s$  and a bin  $b \in s.B$ , we say that item*

$$i \in I \text{ is packed in } b \text{ iff } u_{ib} = 1$$

Given a bin  $b \in s.B$  we can then define structure  $q_b$  as follows

- $J$ : the set of items that are packed inside  $b$
- $Z$ : the set of planes inside  $b$  (section 4.3)
- $T$ : the AABB Tree (section 4.1.1) representing the items inside  $b$

Both sets  $q_b.J$  and  $q_b.T$  contain the items packed in  $b$  but adding and accessing items in  $q_b.J$  has a time complexity of  $O(1)$  given an underlying implementation as HashSet while maintaining  $q_b.T$  usually has a time complexity of  $O(\log(|q_b.J|))$ . The AABB Tree inside this structure is included to allow for fast overlap checks between items and is further explained in sections 4.1.2 and 4.3.1.

#### 4.1.1. AABB Tree

In order to determine the feasibility of a given state, a way of checking for overlaps with items already placed is needed. Since our formulation of the problem only allows for 90 deg rotations over the z-axis. Every item in a solution, by the problem formulation (3.3), is contained inside a bounding box and this box is axis-aligned. An adequate structure to compute overlaps is then an Axis-Aligned Bounding Box Tree (AABB Tree) [1].

AABB Trees are bounding volume hierarchies typically used for fast collision detection and they usually offer a few operations:

- *AABBInsert*( $i$ ): which allows inserting an axis-aligned box  $i$  in the tree
- *AABBOverlaps*( $i$ ): which allows determining if an axis-aligned box  $i$  overlaps an element in the tree
- *AABBClosest*( $i, d$ ): which, given an axis-aligned box  $i$  and a direction  $d \in \{XP, XN, YP, YN, ZP, ZN\}$  along an axis, returns the closest element following that direction starting from the box  $i$

If the tree is properly balanced each operation on average has a time complexity of  $O(\log(n))$  where  $n$  is the number of elements in the tree. Maintaining an AABB Tree in the state allows us to do checks for feasibility during the construction of a solution (as detailed in 4.3.1 ) and feasibility checks on the final states to allow for error detection.

#### 4.1.2. Feasibility

A state  $s$  is said to be feasible if the currently packed items for every bin  $b \in s.B$  aren't overlapping any other item, if they are all contained inside their bin and if each item is either on the ground or satisfies at least one of the support conditions (cond. 1, cond. 2). Since the proposed heuristic is constructive it is more convenient to define the concept of feasibility relative to a change in the state.

**Insertions** Given a state  $s$  and  $b \in s.B$ , an insertion of items is a set of non-overlapping items that are placed in  $b$  and have their  $z_i$  within a tolerance from a certain  $z$ .

**Definition 4.4 (Insertion).** *Given a state  $s$  and a tolerance  $\beta_s$  we define an insertion or placement  $p$  a tuple  $(b, I)$  where  $b$  is a bin and  $I$  is a set of non-overlapping items that are going to be packed in  $b$  such that,  $I \subseteq s.U \wedge \exists z(z \in \mathbb{Z} \wedge \forall i(i \in I \wedge |z_i - z| \leq \beta_s))$*

**Observation 4.2.** *Given a state  $s$  and an insertion  $p = (b, \emptyset)$  where  $b \notin s.B$ ,  $p$  is an insertion which will open bin  $b$  in  $s$ .*

**Definition 4.5 (Next).** *Let  $p$  be an insertion over a state  $s$  we can then define  $s' = \text{Next}(s, p)$  as the "copy" of state  $s$  with  $s'.p = p$ . And  $p$  is then a pending insertion on  $s'$ .*

We can evaluate the changes to the score of a state based on its pending insertion without having to update all the structures for every evaluated state. This property will become apparent in section 4.2. We can then define an algorithm that applies a pending insertion

$p$  on a given state  $s$  with the help of a function  $OpenBin(b)$  which initializes a new structure  $q_b$  with every element at its empty value. The proposed algorithm is shown in 1.

```

input  :  $s$ 
output:  $s'$ 
 $(b, I) \leftarrow s.p$ 
 $s' \leftarrow Clone(s)$  //Memory clone of  $s$ 
if  $b \in s'.B$  then
     $q_b \leftarrow (q_i \in s'.Q : i = b)$ 
     $q_b.J \leftarrow q_b.J \cup I$ 
     $s'.U \leftarrow s'.U \setminus I$ 
end
else Open a new bin
     $s'.B \leftarrow s'.B \cup b$ 
     $s'.Q \leftarrow s'.Q \cup OpenBin(b)$ 
end
 $s'.p \leftarrow \text{none}$ 
return  $s'$ 
  
```

---

**Insertion feasibility** An insertion  $p = (b, I)$  that is pending on a given state  $s$  is feasible if every inserted item  $i \in p.I$  satisfies the constraint of non-overlap (3.16), the constraint of support (3.34) and if it is placed within the size of the given bin.

---

**Algorithm 2:** Is Insertion Feasible
 

---

```

input  :  $b, I, z, I_{support}, I_{upper}$ 
output:  $isFeasible$ 
return  $true$ 
  
```

---

**State feasibility** Describe how to compute the sets efficiently to use the insertion feasibility logic

---

**Algorithm 3:** Is State Feasible
 

---

```

input  :  $s$ 
output:  $isFeasible$ 
return  $true$ 
  
```

---

**Proposition 4.1.** A state  $s'$  derived by committing a feasible insertion  $p$  to a feasible state  $s$  is feasible.

**Observation 4.3.** *We can always define the empty state  $s_e$  where*

$$\begin{cases} s_e.U = I \\ s_e.Q = \emptyset \\ s_e.B = \emptyset \end{cases}$$

*and it is always feasible*

## 4.2. Beam Search

Beam Search (BS) is a heuristic tree search algorithm designed for systems with limited memory where expanding every possible node is unfeasible. The idea behind BS is to conduct an iterative truncated breadth-first search where, at each iteration, only a limited number of  $k$  nodes is expanded. After the expansion, every new node needs to be evaluated and sorted in order to prune the number of nodes down to the  $k$  best ones. The algorithm keeps exploring until no further node can be expanded.

To perform BS one must define the node structure, an expansion function to generate new nodes from existing ones, a ranking between nodes, and a function to determine if a node is final.

A node in the tree can be represented as the state in section 4.1 and eq. (4.1) can be used to determine if a state is final. We also know that a new state  $s'$  derived by  $s$  by applying a feasible insertion  $p$  can be computed as in definition 4.5. This state expansion procedure, with the exception of empty insertions, will generate new states in our tree which will add a positive number of bins or packed items to the solution so, eventually, it will generate a final state.

If the starting state for the search is feasible every new state generated will be feasible and if a final state is found it will be feasible ( proposition 4.1). We also note that starting from state  $s$  the time complexity to compute feasible insertions can be lower than the complexity required to update the structures that will be used for further expansions (AABB Tree insertion and balancing, memory cloning, etc.) so we modified the standard BS algorithm to separate the expansion phase from the commit phase.

Given  $S^0$  the set of initial states and  $k$  the number of best states to expand at each iteration, the described procedure is represented by algorithm 4. As observed in observation 4.3 it's possible to start the search from  $S^0 = \{s_e\}$ .

---

**Algorithm 4:** Beam search

---

```

input :  $S^0, k$ 
output:  $s_{best}$ 
 $S^t \leftarrow S^0$ 
 $S_{final} \leftarrow \emptyset$ 
repeat
   $S^{t+1} \leftarrow \text{Expand}(S^t)$  (algo. 5)
   $S_{final} \leftarrow S_{final} \cup \{s \in S^{t+1} : IsFinal(s)\}$  (def. 4.2)
   $S^{t+1} \leftarrow S^{t+1} \setminus S_{final}$ 
   $S^{t+1} \leftarrow \text{Sort}(S^{t+1})$  (sec. 4.2.1)
   $S^t \leftarrow \emptyset$ 
   $i \leftarrow 0$ 
  forall  $s \in S^{t+1}$  do
     $S^t \leftarrow S^t \cup \text{Commit}(s)$  (algo. 1)
     $i \leftarrow i + 1$ 
    if  $i > k$  then
      break
    end
  end
until  $S^t \neq \emptyset$ 
 $S_{final} \leftarrow \text{Sort}(S_{final})$ 
return first element of  $S_{final}$ 

```

---

**State Expansion** An expansion of a state  $s$  can be seen as a new set of states  $S_{new}$  derived by a set of feasible insertions. In order to determine these insertions, an underlying heuristic is used (described in section 4.3).

The main idea in this phase of the algorithm is to find feasible insertions in all the bins for items that still need to be packed and that are of the same height. With this approach, the solutions given by the algorithm will start by trying to fill lower layers with items of the same height if possible and they'll become more heterogeneous in upper layers where the classes of height will start to mix up. The underlying heuristic will also use a scoring mechanism to select the best insertions for a given class of heights in order to avoid having too many states to sort.

Given a set of items  $I$  and a tolerance  $\beta_s$  we can introduce an algorithm to group them by their shap and produce a set  $G$  of tuples  $(h, I')$  where  $h$  is the hash summarizing the shape of the group and  $I'$  is the set of items grouped as in algo. 6.

Once items are grouped by shape the best insertion for each class of items can be computed for each open bin. If no insertion is possible in any bin, then the only viable insertion is the bin opening insertion (observation 4.2). The described procedure is detailed in algo. 5.

---

**Algorithm 5:** Expand
 

---

**input** :  $S$ 
**output:**  $S_{new}$ 
**forall**  $s \in S$  **do**
 $S_{new} \leftarrow \emptyset$ 
 $G \leftarrow \text{GroupByHash}(s.U)$  (algo. 6)

 $placed \leftarrow false$ 
**forall**  $(h, I) \in G$  **do**
**forall**  $q_b \in s.Q$  **do**
 $P \leftarrow \text{SPBestInsertion}(q_b, I)$  (algo. 7)

**if**  $P \neq \emptyset$  **then**
 $placed \leftarrow true$ 
**forall**  $p \in P$  **do**
 $S_{new} \leftarrow S_{new} \cup \text{Next}(s, p)$  (def. 4.5)

**end**
**end**
**end**
**end**
**if**  $placed = false$  **then**
 $\text{Open a new bin with index } |s.B|$  (oss. 4.2)

 $S_{new} \leftarrow S_{new} \cup \text{Next}(s, (|s.B|, \emptyset))$ 
**end**
**end**
**return**  $S_{new}$ 

---

#### 4.2.1. Scoring States

In order to sort states, a scoring function needs to be defined over them. Since the scoring of the states is what will influence the final solution the most, parameters that are directly related to minimizing the objective function are selected.

In the proposed solution to handle multiple objective functions, lexicographic ordering is used.

---

**Algorithm 6:** Group By Hash

---

```

input  :  $I$ 
output:  $G$ 
 $G \leftarrow \emptyset$ 
forall  $i \in I$  do
     $generate \leftarrow \text{true}$ 
    forall  $(h, I') \in G$  do
        if  $h = \text{hash}(w_i, d_i, h_i)$  then
             $generate \leftarrow \text{false}$ 
             $I' \leftarrow I' \cup i$ 
            break
        end
    end
    if  $generate = \text{true}$  then
         $G \leftarrow G \cup (\text{hash}(w_i, d_i, h_i), \{i\})$ 
    end
end
return  $G$ 

```

---

**Definition 4.6.** Let  $f_1(s), f_2(s), f_i(s), \dots, f_n(s)$  be objective functions ordered by precedence based on index  $i$ , then

$$s < s' \text{ iff } \exists j \in \mathbb{Z} : \begin{cases} f_j(s) < f_j(s') \\ f_k(s) = f_k(s'), \quad \forall k \in \mathbb{Z} : 0 \leq k < j \end{cases}$$

Scoring metrics for each state  $s$  that we want to evaluate can then be computed in the *Next* algorithm by considering the contents of the pending insertions and updating each parameter differentially.

The defined ordering utilized is the following:

- $f_1(s) = -|s.B|$ : we prefer states that opened fewer bins.
- $f_2(s) = \text{avgvol}(s)$ : we prefer states that have packed more average volume between bins.
- $f_3(s) = \text{avgcageratio}(s)$ : we prefer states that have better average cage ratio (eq. (3.1)) between bins.

### 4.3. Support Planes

Support Planes (SP) is a heuristic detailed in the following section based on an underlying 2DBPP heuristic which is used to evaluate feasible insertions starting from a given state. Since the insertions must be feasible SP maintains an internal structure to facilitate the check for feasibility. The idea at the base of SP is to build a solution to the 3DBPP by filling 2D planes called *support planes*.

Each support plane can be characterized by the triple  $S_z = (z, I_{support}, I_{upper})$  where

- $z$ : the height of the plane
- $I_{support}$ : the set of the items that can offer support to items placed on the plane
- $I_{upper}$ : the set of items that will be obstacles to potential new items placed on the plane

Let *coords* be the set of possible coordinate changes which allow for the problem to evaluate insertions starting from different corners of the bin.

Given a function  $IsFeasible(i, bin, I_{support}, I_{upper}, aabb)$  which evaluates if a packing of item  $i$  in bin  $bin$  is feasible, and the function  $ComparePacking(p, p')$  which defines a ranking over insertions in the same plane, the SP algorithm can be written as algorithm 7.

---

**Algorithm 7:** SP Best Insertion

---

**input** :  $s_b, I$   
**output:**  $placement$   
 $placement \leftarrow \emptyset$   
**forall**  $S_z \in planes$  **do**  
     $I_p \leftarrow I \setminus \{i \in I : z + i.h > H_b\}$   
    **forall**  $change \in coords$  **do**  
         $I'_{upper} \leftarrow CoordinateChange(change, I_{upper})$   
         $I'_p \leftarrow CoordinateChange(change, I_p)$   
         $P' \leftarrow SPPackPlane(W_b, D_b, I'_{upper}, I'_p)$  (Algorithm 8)  
         $P \leftarrow CoordinateChange(change, P')$   
         $P \leftarrow \{i \in P : IsFeasible(i, bin, I_{support}, I_{upper}, aabb)\}$   
        **if**  $ComparePacking(placement, P)$  **then**  
             $placement \leftarrow P$   
        **end**  
    **end**  
    **if**  $placement \neq \emptyset$  **then**  
        **return**  $placement$   
    **end**  
**end**  
**return**  $placement$ 

---

To evaluate a packing on a plane a heuristic to solve the 2DBPP is used with the introduction of fixed insertions which represent items on other planes that will be obstacles in the current one.

Given the dimensions of the 2D bin  $(W_b, D_b)$ , the set of obstacles  $I_o$  and the set of items to pack  $I_p$  a new insertion can be computed following algorithm 8

---

**Algorithm 8:** SP Pack Plane

---

**input :**  $W_b, D_b, I_o, I_p$ **output:**  $P$  $P \leftarrow \emptyset$  $2dPacking \leftarrow \emptyset$ **foreach**  $i \in I_o$  **do**    //Initialize the 2D bin packing instance with each obstable already  
    placed     $2DPlaceRect(2dPacking, i)$ **end****repeat**

//Pack untill full

 $p \leftarrow 2DPackRect(2dPacking, W_b, D_b, i)$      $P \leftarrow P \cup \{p\}$ **until**  $p \neq \emptyset$ **return**  $P$ 

---

**Commit Extension** We now describe an extension to *Commit* (algo. 1) to update the structures needed by SP.

When a plane is filled, new insertions become less likely to be feasible. To avoid evaluating planes where no insertion is possible a mechanism to prune dead planes can be introduced.

Since best insertions for a bin are always evaluated by considering lower planes first, if all the insertions in *Expand* (algo. 5) happened over a  $z_{min}$  then we can safely remove the opened planes with  $z < z_{min}$  for that bin. Let us introduce a  $z_{min}$  variable carried over in  $q_b$  for each bin, which is updated during the *Expand* phase with the minimum  $z$  of all the insertions on bin  $b$ . Once the best states are computed and *Commit* is called we can then use its value to prune planes in each  $q_b$ . Other operations are also necessary in the *Commit* algorithm to allow SP to update its data structures accordingly to the insertion.

Given a state  $s$  and an insertion  $p$  where each packed item  $i \in p.I$  in bin  $b$  has  $z_i$  within tolerance of  $z$  and the minimum height for the considered bin  $q_b.z_{min}$ . The algorithm which updates the structures for a given bin  $b$  is represented by algorithm 9. This new algorithm can be used as the last step of the *Commit* algorithm for each  $b \in s'.B$ .

---

**Algorithm 9:** SP Apply and Filter
 

---

```

input  :  $s, p, z, z_{min}, \beta_s$ 
output:  $s$ 
 $q_b \leftarrow (q_i \in s.Q : i = p.b)$ 
//Filter bad planes
 $q_b.Z \leftarrow q_b.Z \setminus \{(z', I_{support}, I_{upper}) \in q_b.Z : z' < z_{min}\}$ 
//Apply insertion
forall  $i \in p.I$  do
   $q_b.T \leftarrow InsertAABB(i, q_b.T)$  //If balanced  $O(\log(n))$ 
   $generate \leftarrow true$ 
  forall  $(z', I_{support}, I_{upper}) \in q_b.Z$  do
    //Based on the distance from the top of the item
     $dz \leftarrow z' - (z_i + h_i)$ 
    if  $0 \leq dz \leq \beta_s$  then
       $generate \leftarrow false$ 
       $I_{support} \leftarrow I_{support} \cup i$ 
    end
    else if  $dz < 0$  then
       $I_{upper} \leftarrow I_{upper} \cup i$ 
    end
  end
  if  $generate$  then
     $q_b.Z \leftarrow q_b.Z \cup (z_i + h_i, \{i\}, \emptyset)$ 
  end
end
return  $s$ 

```

---

#### 4.3.1. Scoring Insertions

# 5 | Computational experiments

In this chapter in section 5.1 we evaluate the proposed heuristic against the MILP model (3.1) and in section 5.2 against other heuristic from the literature. We then show the effectiveness of our approach for our case study in section 5.3. All the tests were run on a desktop computer with an AMD Ryzen-7 5800x processor with 8 cores at 3.8 GHz and 32GB of DDR4 system RAM with Windows 10. The algorithm was implemented in Java 11 and the model was run using the python APIs from CPLEX Optimization Studio 22.1.0. In every test CPLEX was used with a maximum runtime of 1 hour. Each evaluation against the heuristic lists both operational modes described in ?? listed as "Order By Hash" and "Single Placement". All the instances used in each section of this chapter are available at <https://github.com/artumino/BinPackingThesis/tree/main/tests/instances>. Out of the 100 instances used for our case study experiments, only 80 were freely sharable with the generation procedure also described in section 5.3.

## 5.1. Model validation

We compared our heuristic to the proposed MILP model of section 3.1 with a single bin and with no limit on the height of the bin (also referred to the 3D strip packing problem). The heuristic was configured to run without vertex support, using only area support rules for its feasibility checks and  $k$  was set to 200. The configured parameters for the test were  $\alpha_s = 0.7$ ,  $\beta_s = 5$ , and the discretization unit for the model was  $\delta = 10$ . Tests were run on the first instance of the class 1 problems of the literature tests described in section 5.2. The test was run with an iterative approach by selecting only a limited ammount of items from the selected instance starting from 1 item and increasing the number of items to pack by one at each iteration. Starting from instance with 6 boxes to pack, the solution from the previous instance of the problem was used to mip start the new one to allow for lower execution times. Table 5.1 shows the obtained  $z_{\max}$  value of the heuristic and the MILP solution, the runtime in seconds and the number of items. Since the underlying problem is NP-Hard it is shown that starting from instances of size bigger than 8 items, the MILP model becomes too slow for practical use while our heuristic mantains a negligible

execution time. Due to discretization errors, some of the model instances gave solutions that didn't have the expected ammount of support and are marked with an asterix. The solution to instance number 5 and instance number 7 is also shown in fig. 5.1.

Table 5.1: Comparison with MILP model on limited set of boxes

N	Group By Hash		Single Placement		MILP Model	
	Max Z	TT(s)	Max Z	TT(s)	Max Z	TT(s)
1	85	0.00	85	0.00	85	0.01
2	85	0.00	85	0.00	85	0.09
3	85	0.00	85	0.00	85	0.24
4	85	0.01	85	0.01	85	0.64
5	85	0.02	85	0.02	85	16.48
6	158	0.06	158	0.05	158*	594.32
7	158	0.07	158	0.08	158*	3,178.00
8	160	0.10	160	0.08	-	-
9	169	0.09	161	0.10	-	-
10	218	0.12	218	0.13	-	-
11	240	0.12	240	0.12	-	-
12	310	0.13	316	0.16	-	-
13	310	0.15	333	0.18	-	-
14	310	0.20	333	0.22	-	-
15	406	0.21	397	0.27	-	-
16	435	0.23	452	0.36	-	-
17	429	0.27	515	0.41	-	-
18	432	0.32	522	0.47	-	-
19	458	0.35	522	0.55	-	-
20	539	0.37	564	0.62	-	-

\* Some boxes had lower support than expected due to discretization errors within the  $0.65 \leq \alpha_s \leq 0.7$  range.

## 5.2. Literature results

The heuristic was also evaluated against instances from the literature defined by Martello et al.. Since these instances were designed for heuristics without the vertical support constraint and without orthogonal rotations we ran the experiments with a relaxed version of our constraints. The heuristic was configured to ignore the support constraint with  $\alpha_s = 0$  and  $\beta_s = 1$ . We also disable orthogonal rotations and stopped scoring insertions based on the support area available (as described in section 4.3.1).

The literature instances are divided in classes from 1 to 8 with each class having a different

(a) MILP, Instance 5

(b) Heuristic  $k=200$ , Instance 5

(c) MILP, Instance 7

(d) Heuristic  $k=200$ , Instance 7

Figure 5.1: Graphical comparison between solutions from the heuristic and from the MILP model

bin size and various distributions of types of items. Instances were generated with the C++ instance generator provided by Martello et al. which allows the generation of problem instances given a problem class and the number of items to use. We generated 10 instances for each pair of problem class and number of items  $n \in \{50, 100, 150, 200\}$ .

In table 5.2 (and more in depth in table A.21) we compare the average number of opened bins across 10 instances for each problem class and  $n$  number of items combination. The results are then compared to the most effective methods from the literature listed as TS3 [8], GLS [4], GASP [2], GVND [11], EHG2 [6], BRKGA [5], BRKGA-VD [12] and ordered by publishing date. Best values of all the heuristics are marked in bold. Best scoring values across different configurations of our heuristic are instead marked in italic. Results show an average gap of 4.1% compared to the average value across the other heuristics and an average gap of 5.32% across the values from the best performing one.

### 5.3. Case study results

Case study experiments were conducted on a series of problem instances that were divided between 20 real world instances and 80 generated instances based on a sampling of an anagraphic of real world products. Each instance was anonymized and converted to a format similar to the one used for the literature tests thanks to a Rust program available at <https://github.com/artumino/BinPackingThesis/tree/main/additional/testConverter>. Support parameters for the heuristic was set to  $\alpha_s = 0.7$  and  $\beta_s = 10$  with both area and vertex support enabled, with dimensions for the bin, for the items and for the tollerances assumed to be in millimeters. Different values of  $k \in \{1, 5, 10, 20, 50, 100, 200\}$  were tested as well as both placement modes.

Each generated instance is composed of a random number of  $N$  items sampled from a given range of possible instance sizes. All generated instances had a bin of standard size  $800 \times 1200 \times 2000$ . We identified four ranges of interest and generated 20 instances for each range as follows:

- **Class 1-20:** a class of instances with the target sizes for our case-study  $N \in [70, 100]$
- **Class 21-40:** a class of small sized instances with number of items  $N \in [50, 70]$
- **Class 41-60:** a class of medium sized instances with number of items  $N \in [70, 120]$
- **Class 61-80:** a class of big instances with number of items  $N \in [120, 200]$

Given an input  $N$  (the size of the test instance), the generation procedure uniformly sampled an item type from an anagraphic of real-world products. The number of items

Table 5.2: Literature results for k=50

Class	n	Group by Hash k=50	Single Placement k=50	TS3	GLS	GASP	EHGH2	GVN	BRKGA	BRKGA-VD

of that type to add to the test instance was then sampled from a normal distribution  $\mathcal{N}(\mu = 4.6, \sigma = 1.8)$ , floored to be an integer value and clamped to avoid generating more items than  $N$ . This uniform sampling of item types was done until the instance was composed of  $N$  items.

Real world instances are listed as **Class 81-100** and have a variable number of items between  $[25, 345]$ , a variable bin size (although similar to the one used for the generated instances), and a variable number of items of the same type with homogeneous instances with only a few unique types of items and instances with every item of a different type. An example of real world instances is shown in fig. 5.2 where items of the same shape are marked with the same color.

Table 5.3 shows the average results over the 20 instances per class, divided by each configuration of the heuristic with different values of  $k$ . The results shown include the total execution time in milliseconds (TT), the number of opened bins (B) and the average cage ratio between the opened bins (CR). It is clear that although the "Single Placement" method had better results when dealing with a relaxed version of the problem, grouping items by type shows considerable improvements under all measured metrics when taking support into account. Most of the configurations lead to an average cage ratio of more than 70%, which was the target value for our case study. It is also possible to see that increasing the value of  $k$  improves the quality of the solutions, on average, at the expense of a higher execution time. By doing a case by case analysis of the each experiment we discovered that in some instances increasing  $k$  can temporarily worsen the solution. A further study of the problematic instances highlighted that the current greedy scoring mechanism of the states can lead to cutting out good solutions too early. Further improvements are considered in chapter 6.

## List of Figures

3.1	Cage ratio of two different bin configurations . . . . .	6
3.2	Rappresentation of an item with vertical support given $\alpha_s = 0.5, \beta_s$ . . . .	6
3.3	Coordinate system representation for a generic item $i$ and it's rotated clone $i \in I^R$ . . . . .	8
5.1	Graphical comparison between solutions from the heuristic and from the MILP model . . . . .	27
5.2	Solutions of case study tests with the "Group by Hash" placement and $k = 200$ . . . . .	32

## List of Tables

5.1	Comparison with MILP model on limited set of boxes . . . . .	26
5.2	Literature results for k=50 . . . . .	29
5.3	Average execution time of literature results with bin gap . . . . .	30
5.4	Summary of use-case tests . . . . .	31
A.1	Case study results 1-5 . . . . .	38
A.2	Case study results 6-10 . . . . .	39
A.3	Case study results 11-15 . . . . .	40
A.4	Case study results 16-20 . . . . .	41
A.5	Case study results 21-25 . . . . .	42
A.6	Case study results 26-30 . . . . .	43
A.7	Case study results 31-35 . . . . .	44
A.8	Case study results 36-40 . . . . .	45
A.9	Case study results 41-45 . . . . .	46
A.10	Case study results 46-50 . . . . .	47
A.11	Case study results 51-55 . . . . .	48
A.12	Case study results 56-60 . . . . .	49
A.13	Case study results 61-65 . . . . .	50
A.14	Case study results 66-70 . . . . .	51
A.15	Case study results 71-75 . . . . .	52
A.16	Case study results 76-80 . . . . .	53
A.17	Case study results 81-85 . . . . .	54
A.18	Case study results 86-90 . . . . .	55
A.19	Case study results 91-95 . . . . .	56
A.20	Case study results 96-100 . . . . .	57
A.21	Summary of opened bins by heuristic . . . . .	58

# List of Symbols

Variable	Description	SI unit
$\boldsymbol{u}$	solid displacement	m
$\boldsymbol{u}_f$	fluid displacement	m
